

Stable HVA identity versus within-V1 probe identity

Primary test: does HVA label explain more session-level variance? Dots below are sessions; V1 probes are categorical locations, not hierarchy scores.

A Identity effect sizes (whole-session bootstrap)

B Direct identity contrast

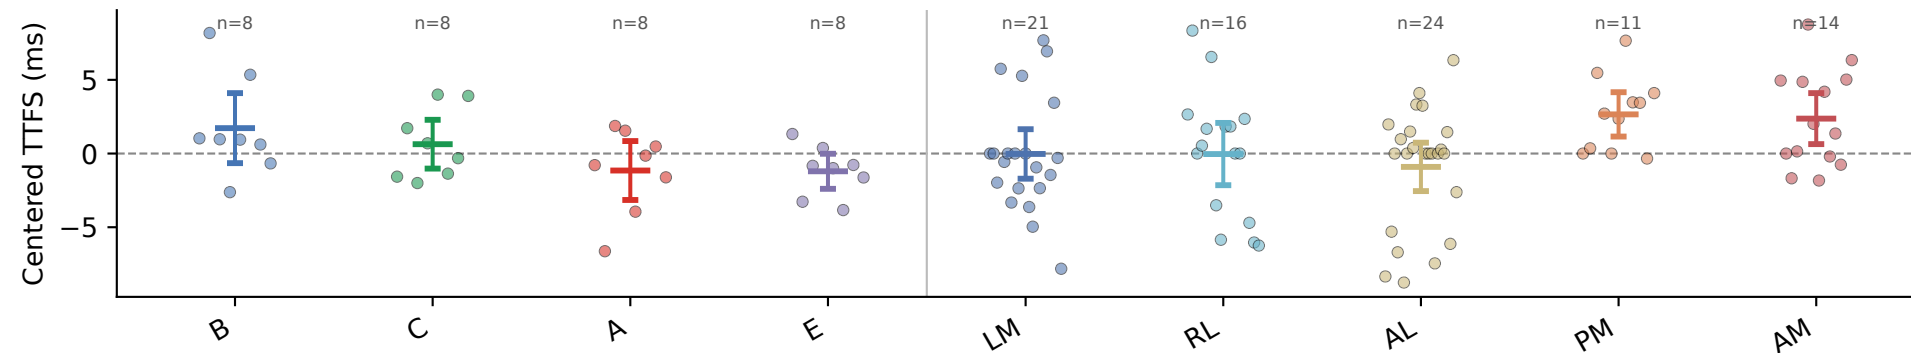

Primary conclusion

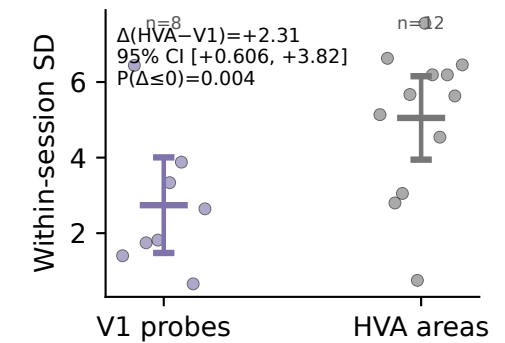

All three $\Delta\omega^2$ intervals cross zero.

Current data do not establish that HVA identity explains more variation than V1 probe identity.

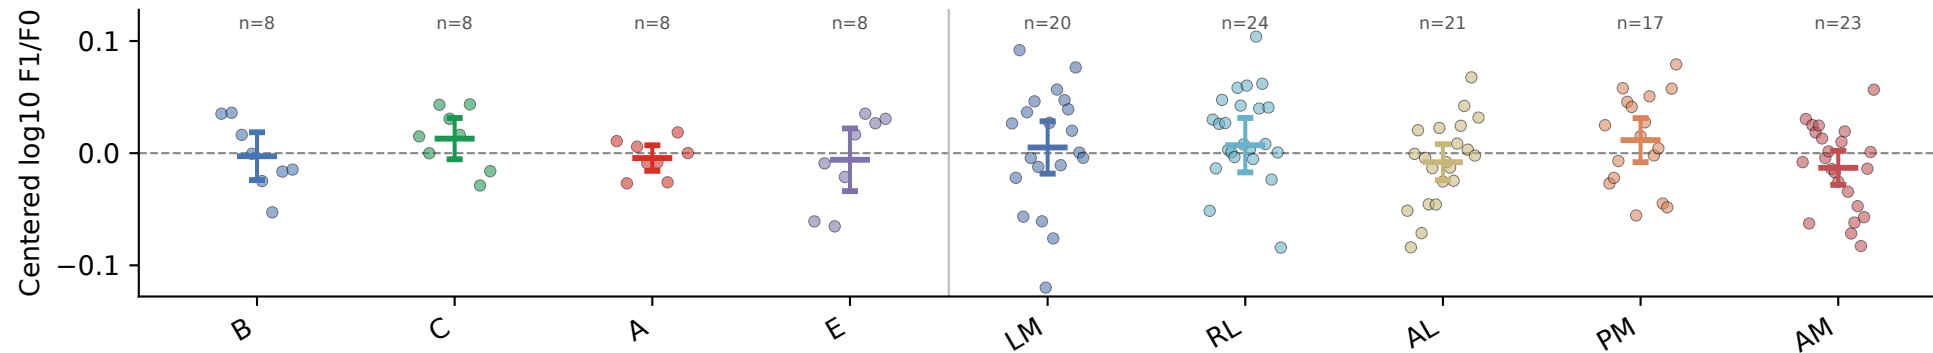

C1 TTFS (ms): session-centered group means

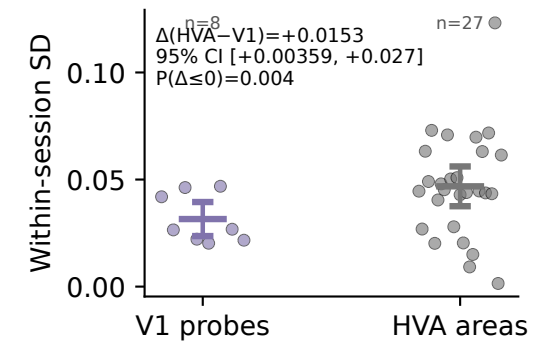

D1 Diagnostic: session SD

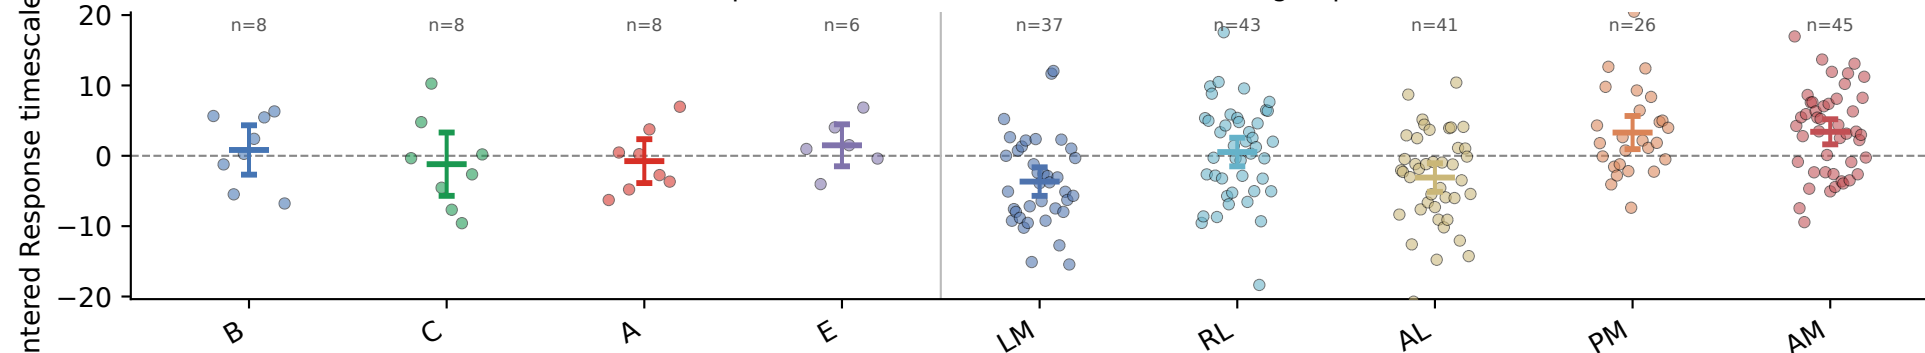

C2 log10 F1/F0: session-centered group means

D2 Diagnostic: session SD

C3 Response timescale (ms): session-centered group means

D3 Diagnostic: session SD
